CORGI / PRODUCT IDEAS

# Four products I would be excited to build

A few practical ideas across enterprise sales and the customer experience. The common thread is simple: take a real insurance workflow and make it easier, safer, or much faster.

| | |
|---|---|
| 01 | **Partner Launch Studio**<br>Make enterprise partnerships easier to scope, test, and launch. |
| 02 | **Partner Sandbox**<br>Let a prospective partner experience what Corgi could look like inside its product. |
| 03 | **Driver Accident Response**<br>Make the first few minutes after a trucking accident simple and digital. |
| 04 | **Policy Wallet**<br>Give fleet customers one simple place for certificates, vehicles, drivers, documents, and policy actions. |

How I am thinking about it
I am not assuming any of these are missing from Corgi today. I am using Corgi's public product and engineering direction as a starting point, then looking for useful extensions I could own end-to-end.

01 IDEA

# Partner Launch Studio

I would build a workspace that connects the commercial deal to the technical launch.

Why I would build this
Corgi's enterprise motion involves partnerships with platforms such as TMS, ELD, load-board, factoring, fuel-card, and compliance companies. I would build the software layer that keeps commercial, product, engineering, compliance, and launch work moving in one place.

## Simple example: Acme TMS wants to embed Corgi.

Instead of keeping the deal, integration scope, testing status, and launch checklist in separate tools, the partner gets one live view of where the launch stands.

**Partner** → **Scope** → **Integrate** → **Certify** → **Launch**

### What I would build

- Partner profile with products, regions, business model, and key contacts.
- Commercial and technical requirements in one place.
- Integration checklist tied to actual API work.
- Launch readiness with clear blockers and owners.

### How I would approach it

- Connect partner records to tasks, API environments, and test runs.
- Keep every requirement versioned and auditable.
- Give sales and engineering the same source of truth.
- Start with one partner type and grow from there.

What the value would look like
The goal is not another CRM. It is to make a signed partnership easier to turn into a working Corgi integration, with fewer handoffs and fewer surprises before launch.

Public context: Corgi describes embedded partnerships and a sales-engineering role focused on partner integrations and enablement.

02 IDEA

# Partner Sandbox

I would let a potential partner actually experience the Corgi insurance flow before committing to a full integration.

Why I would build this
A technical partnership is easier to sell when the partner can see the experience instead of imagining it from API documentation. I would build a realistic sandbox where a TMS, fleet platform, or other partner can test a Corgi-style quote, bind, and certificate journey.

## Simple example: show Corgi inside Acme TMS.

A partner enters a sample fleet, requests a quote, accepts it, and generates a certificate - all inside a safe test environment that behaves like a real integration.

**Fleet data** → **Quote** → **Accept** → **Bind** → **COI**

### What I would build

- Reusable sample-data templates for different partner types.
- Embeddable quote and policy experiences.
- Test accounts and realistic API responses.
- A simple “what would production require?” summary.

### How I would approach it

- Build against mock APIs first, then plug into approved Corgi sandbox interfaces.
- Capture the exact calls and data used during the demo.
- Generate a technical handoff from the sandbox session.
- Keep the demo environment isolated from production.

What the value would look like
The value is speed: a prospect can understand the customer experience and the technical scope in one session, while engineering gets a clearer starting point for the real integration.

03 IDEA

# Driver Accident Response

I would make the first few minutes after a trucking accident simple enough that a driver can complete the process from a phone.

Why I would build this
The driver should not have to search for a policy number, figure out what documents matter, or write a long report while standing at an accident scene. The app would guide the driver step by step and turn the result into a structured claim intake.

## Simple example: “I had an accident.”

The driver confirms safety, shares location, takes photos, records a short voice note, answers a few questions, and submits. The system creates one organized incident file for the claims team.

**Safe?** → **Location** → **Photos** → **Voice note** → **Submit**

### What I would build

- Fast mobile-first accident flow with no heavy setup.
- Automatic location, time, vehicle, and policy context where authorized.
- Photo and document collection with clear prompts.
- A structured incident timeline visible to the claims team.

### How I would approach it

- Start with a mobile web experience so there is no app-store friction.
- Use speech-to-text for the driver statement, then let the driver edit it.
- Generate a structured FNOL package and audit trail.
- Keep consequential coverage and claim decisions with licensed professionals.

What the value would look like
The value is a cleaner first notice of loss: less back-and-forth, better evidence at the start of the file, and a much easier experience for the person who is actually dealing with the accident.

04 IDEA

# Policy Wallet

I would give fleet customers one simple mobile place for the everyday insurance tasks they need most.

Why I would build this
Insurance is usually something customers touch only when they need a certificate, add a vehicle, update a driver, find a document, or report a problem. I would make those actions feel more like a useful product and less like policy administration.

## Simple example: “Send a certificate to ABC Logistics.”

The customer selects the vehicle, chooses the certificate holder, confirms the recipient, and sends it. The same place also shows active vehicles, drivers, documents, renewal tasks, and open requests.

**Find** → **Select** → **Confirm** → **Send** → **Track**

### What I would build

- One-tap access to COIs and policy documents.
- Fleet and driver list tied to the insurance relationship.
- Simple requests for changes, documents, and support.
- Clear status for anything still waiting on Corgi.

### How I would approach it

- Make common actions extremely short - three or four taps where possible.
- Use secure identity and permission checks before any policy action.
- Keep every request and response auditable.
- Start with the highest-frequency customer actions and add more over time.

What the value would look like
The value is everyday usefulness. A fleet owner has one place to get proof of insurance, keep track of fleet details, complete requests, and see what still needs attention - without having to navigate a large insurance portal.

Public context: Corgi publicly describes customer-facing policy management and same-day policy actions, while its trucking roles describe policy servicing, endorsements, and renewals. NOTES

# How I would approach these ideas

These are product and engineering directions, not claims about gaps in Corgi's current software. I would validate the actual workflow with the team before building against real systems or data.

| | |
|---|---|
| **Partner Launch Studio** | Best fit if the goal is to improve the path from enterprise partnership to production launch. |
| **Partner Sandbox** | Best fit if the goal is to make technical sales and partner discovery more tangible. |
| **Driver Accident Response** | Best fit if the goal is to create a simple, high-impact customer experience around claims intake. |
| **Policy Wallet** | Best fit if the goal is to make frequent customer actions faster and easier on mobile. |
